Day 58 - AI Feature Proposal

AI roadmap | Innovation proposal | Future architecture

Objective and scope

This proposal outlines how ZECPATH AI could explore future interview capabilities while building on its modular resume, scoring, screening, and interview workflow. The features and architecture described here are proposals; they are not presented as implemented system capabilities.

1. AI Roadmap

Foundation

Begin by reviewing the current project modules and documenting the intended interview workflow. Identify what candidate, role, interview, and rubric information each feature needs; define who can access it, how long it is retained, and where human review is required. Set evaluation criteria before building prototypes. The foundation phase is complete when the workflow, data boundaries, and review responsibilities are clear.

Prototype

Start with role-based interview coaching and transcript or rubric summaries. Use sample or consented data, and compare outputs with human reviewers to find missing evidence, unsupported statements, and confusing feedback. Explore video analysis separately. Treat emotion detection as research only and keep it out of candidate scores. Proceed when reviewers can assess the outputs and their limitations.

Limited pilot

Trial selected features with a small, defined set of roles and interviews. Track summary quality against human review, rubric coverage, response time, reliability, reviewer corrections, and candidate or interviewer feedback. Set acceptable targets before the pilot begins; use the results to decide whether each feature should expand, change, or pause.

Scale and monitor

Expand successful features gradually across additional roles or interview stages. Continue monitoring quality, latency, errors, and reviewer corrections as usage grows. Reassess the feature when the workflow, input data, or model changes, and keep a practical way to revise or disable it if performance no longer meets the agreed goals.

Roadmap decision principle

> **Move from one phase to the next only after its review gate is met. Coaching results remain separate from hiring evaluation throughout the roadmap, and AI outputs support the workflow rather than replace human judgment.**

2. Innovation Proposal

Proposed features for candidate preparation, interview quality, and hiring workflow visibility.

AI coaching system

The coaching system would let candidates practise questions related to a specific role and receive feedback tied to the job's stated competencies. It could identify where an answer is clear, incomplete, or missing a concrete example, then suggest a focused practice topic. Practice results should remain private to the coaching experience and should not flow into the employer's hiring score.

Candidate improvement suggestions

After an interview has been reviewed, ZECPATH AI could help prepare useful, specific feedback for a candidate. Suggestions should refer to the reviewed interview evidence and offer practical next steps, such as practising a technical explanation or providing a clearer example. A human reviewer should check the feedback before it is shared, so inaccurate or unsupported comments are corrected.

Interview analytics dashboard

A dashboard could show interview progress, completion of required rubric areas, and reviewer scores by competency. It could flag incomplete evaluations and help teams understand where interview stages are delayed. The dashboard should make the evidence and review status easy to inspect; its summaries are for workflow support, while people remain responsible for candidate decisions.

Additional improvement areas

Real-time feedback could offer an interviewer an optional prompt when a stated rubric topic has not yet been covered. The interviewer remains in control of the conversation and can accept or dismiss each suggestion.

AI video analysis could be explored as an optional way to summarize defined interview evidence from a recording. Any prototype should be evaluated separately and should avoid inferring personality or job suitability from a candidate's appearance.

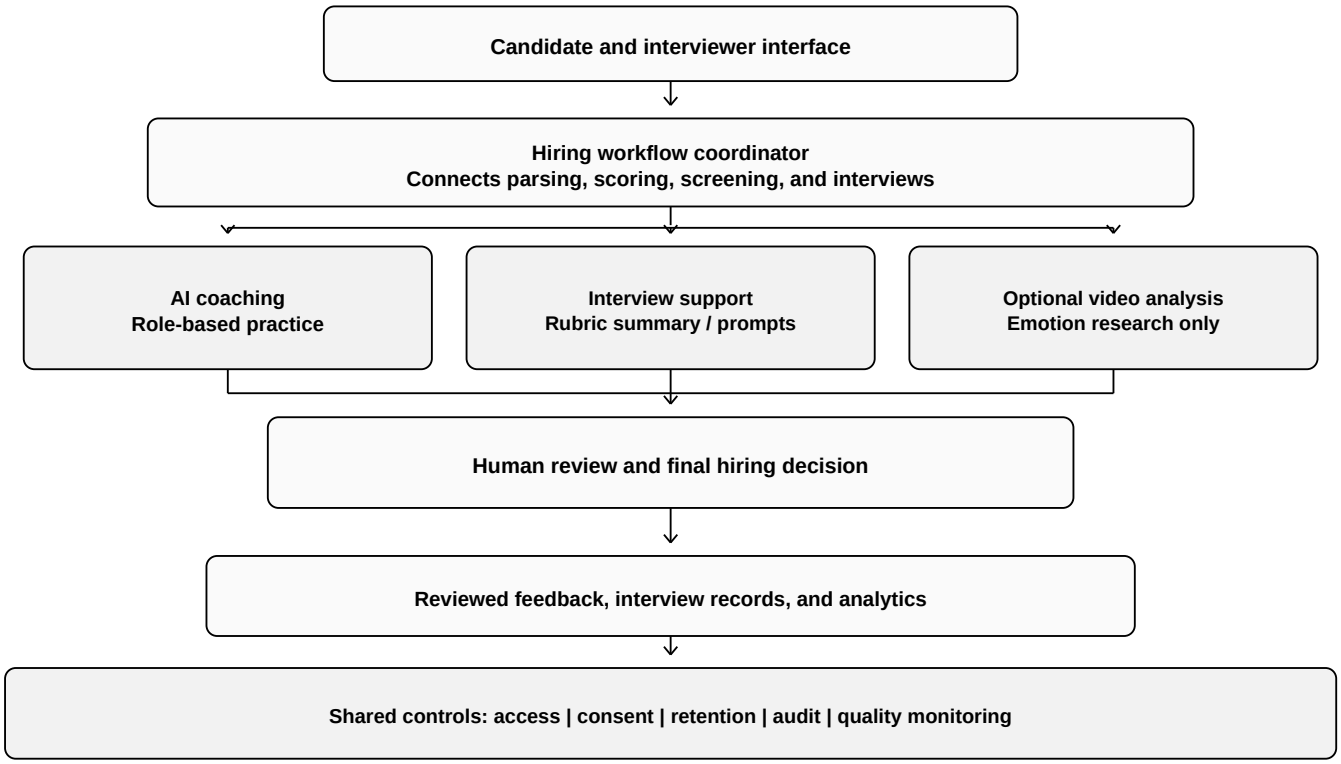
Emotion detection should remain an exploratory research question. Inferred emotions should not be used as a candidate score or as a basis for a hiring decision.

Expected innovation outcome

> **Together, these ideas aim to make interview preparation more useful, reviewer workflows more complete, and feedback more actionable, while preserving human responsibility for evaluation and decisions.**

3. Future Architecture Ideas

A proposed modular design can connect the current pipeline to future interview services without treating every capability as one large feature. The flow below is conceptual and should be refined during the foundation phase.



Workflow coordination

A hiring workflow coordinator could pass structured role, candidate, interview, and rubric information between the resume, scoring, screening, and interview components. A defined interface would let each proposed capability be tested or updated independently.

Separate AI services

Coaching, transcript and rubric analysis, real-time interviewer prompts, and optional video analysis should be separate capabilities. This makes it possible to pilot the lower-risk workflow features first while keeping video and emotion-related exploration isolated and optional.

Data, audit, and operations

Store only information needed for the agreed workflow, apply access and retention controls, and record AI outputs, model versions, and human corrections. Monitor output quality, response time, failures, and reviewer feedback. The system should allow a feature to be revised or disabled if it falls below its agreed quality goals.

Human decision boundary

AI may assist with practice, summaries, and workflow insights. Human reviewers remain responsible for evaluating candidates and making final hiring decisions. Inferred emotion is excluded from candidate scores and decisions.

Pilot measures

Before a pilot, define targets for agreement with human-reviewed evidence, rubric coverage, reliability, response time, reviewer corrections, and candidate or interviewer feedback. Use those results as the gate for expanding, revising, or stopping each feature.
